

# Translation

**The process**  
**from**

**m-RNA**  **polypeptide chain**

# Accessories required: -

- **m-RNA**
- **Ribosomes**
- **t-RNA**
- **Aminoacids**
- **Aminoacyl t-RNA synthetases**
- **Different factors (IF, EF, RF) and Enzymes**
- **Energy (ATP, GTP)**

# Aminoacylation

Attachment of amino acids to t-RNA

**GCC  
GCU  
GCA  
GCG  
Alanine**

Enzyme required

Aminoacyl t-RNA synthetase

**(20)**

Due to degeneracy of Genetic code, All the t-RNA that are specific for a particular amino acid must have a common recognition site for the respective aminoacyl t-RNA synthetase enzyme.

# Translation comprises of 3 steps:

- **Initiation**
- **Elongation**
- **Termination**

- Almost same in both prokaryotes and eukaryotes

## *Initiation requires special signals :*

**In prokaryotes** – Shine-Dalgarno sequence (purine rich; 8-12 nucleotides upstream from initiation codon)

Shine & Dalgarno  
sequence (Purine rich)

## Initiation requires special signals :

In eukaryotes – No Shine-Dalgarno sequence; have

- 1) 5' cap
- 2) Leader sequence (between 5' cap and initiating AUG; usually < 100 bases)
- 3) 3' trailer sequence (~1000 bases) and poly A tail (recently known tail and tail binding protein may take part)

## **In Prokaryotes**

3 Initiation Factors (IF1, IF2 and IF3)

## **In eukaryotes**

probably 9 Initiation factors (including eIF-4A  
and eIF-4B)

Initiation codon: AUG codes for methionine

## In prokaryotes

Methionine is of special form  $\longrightarrow$  formyl methionine

Methionyl t-RNA synthetase

1) t-RNA + methionine  $\longrightarrow$  methionyl t-RNA

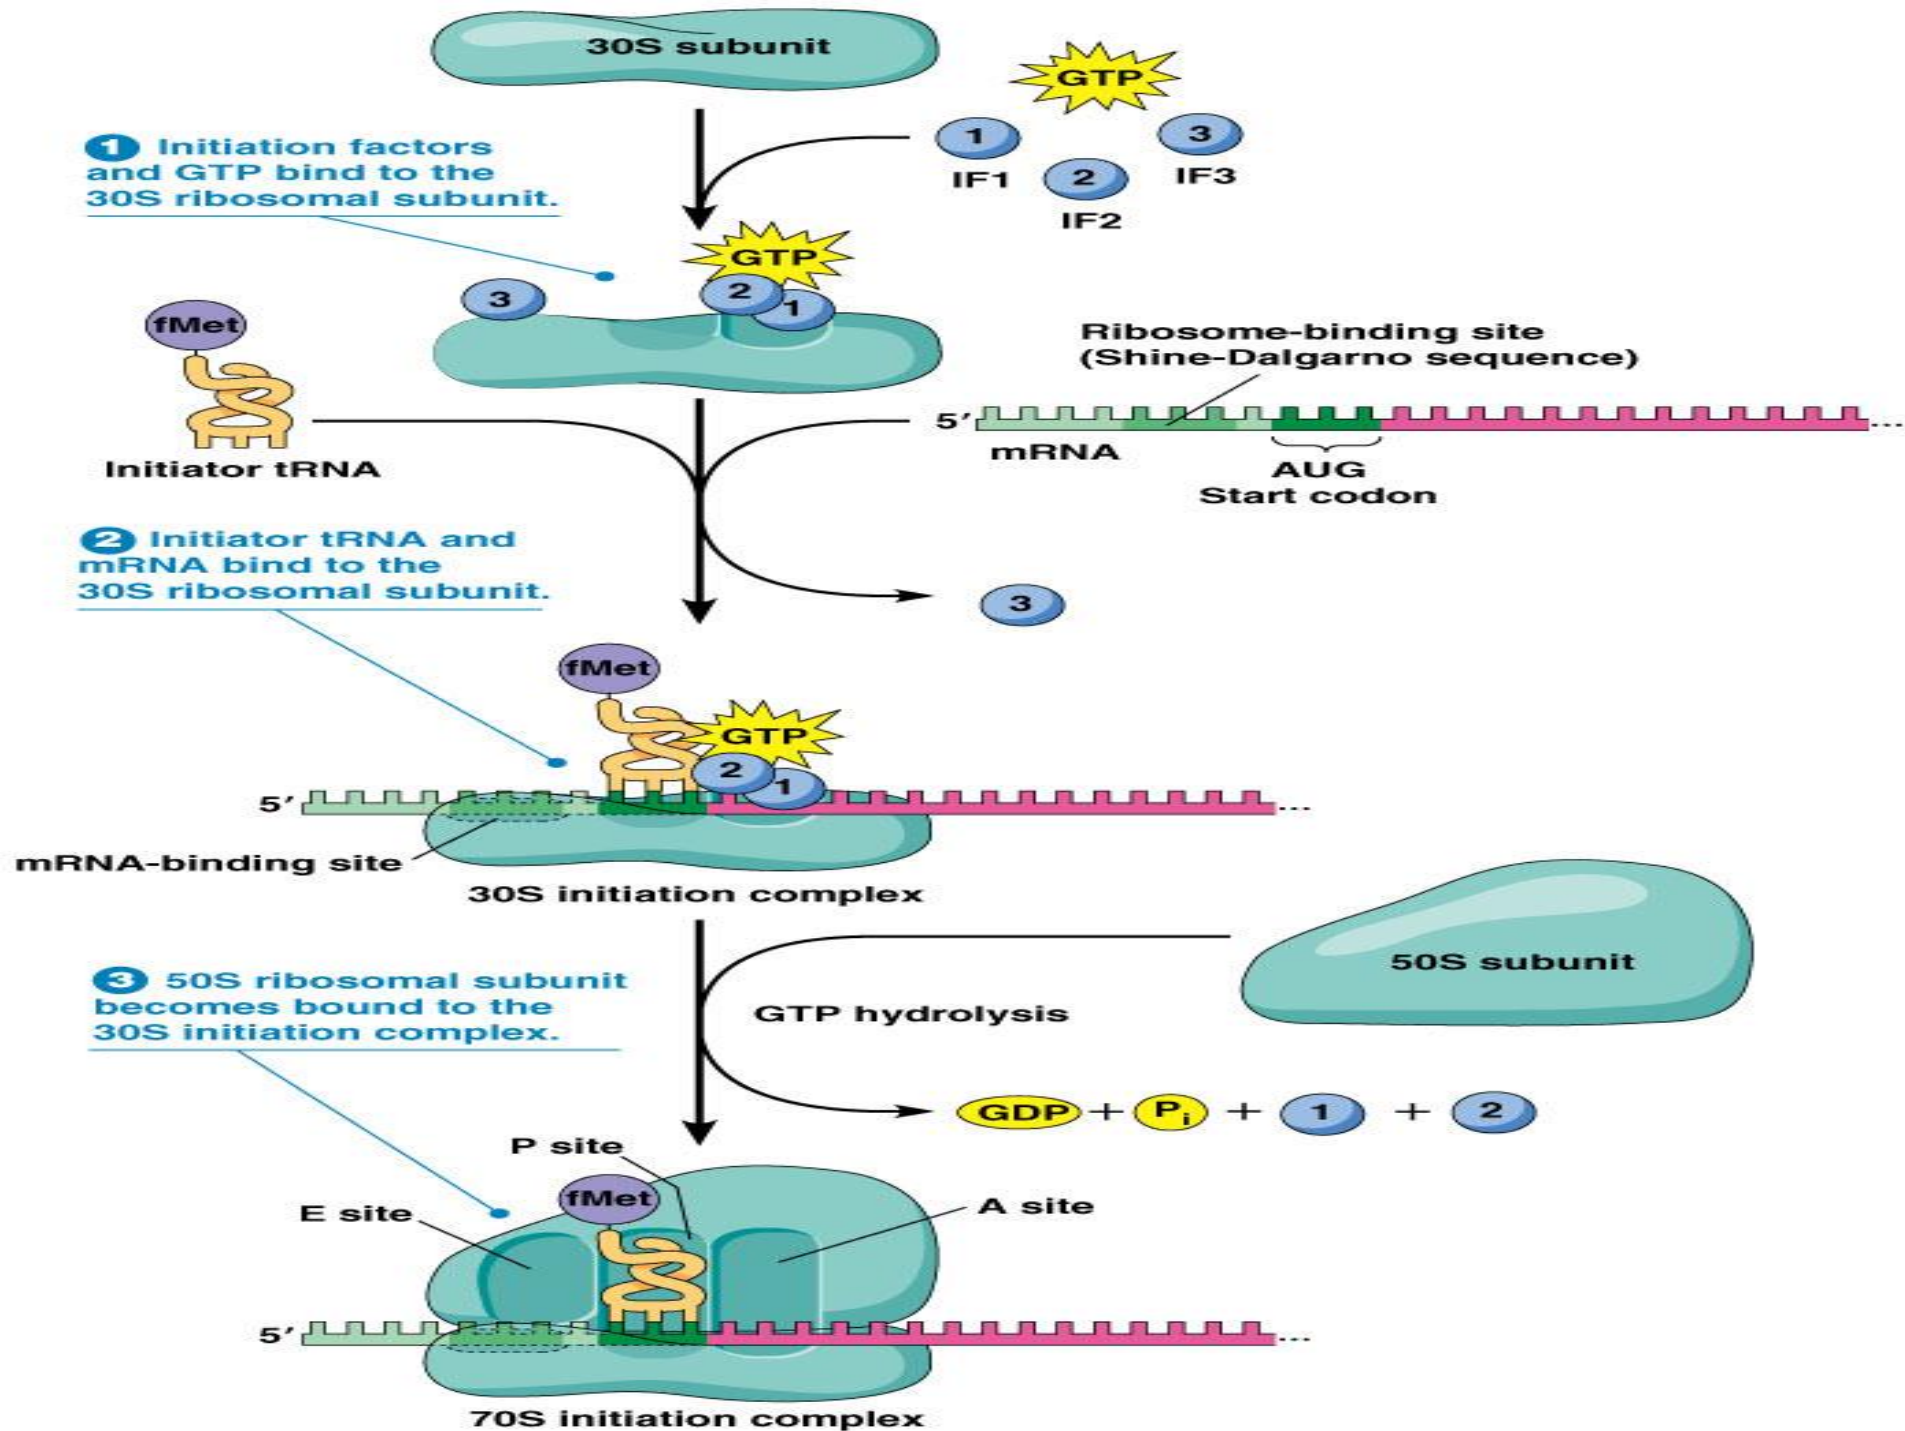

Transformylase

2) methionyl t-RNA  $\longrightarrow$  **f-met-t-RNA<sub>f</sub><sup>met</sup>**

In eukaryotes, no transformylase enzyme,

so, methionine is not formylated

# Exactly where the m-RNA lies in intact ribosome ?

not known

could be:

fits into the space between 2 subunits of ribosome

or

lies slightly embedded in the smaller subunit

**It must lie in a manner that the codons are sufficiently exposed for aminoacyl t-RNA to recognize and bind**

**Ribosome dimension ( $\sim 250\text{\AA}$ ) enough to cover 30-40 bases of m-RNA i.e., 10-13 codons lie inside**

**Out of these only two codons are at any given time involved in protein synthesis**

## *Initiating t-RNA is also special*

In prokaryotes it is **t-RNA<sub>f</sub><sup>met</sup>**

In eukaryotes it is **t-RNA<sub>i</sub><sup>met</sup>**

Both are structurally different from **t-RNA<sup>met</sup>**  
that is specific for internal AUG

## t-RNA<sub>f</sub><sup>met</sup> have

- 1) a series of 3 G-C pairs in anticodon arm and
- 2) 5 unpaired bases in acceptor arm

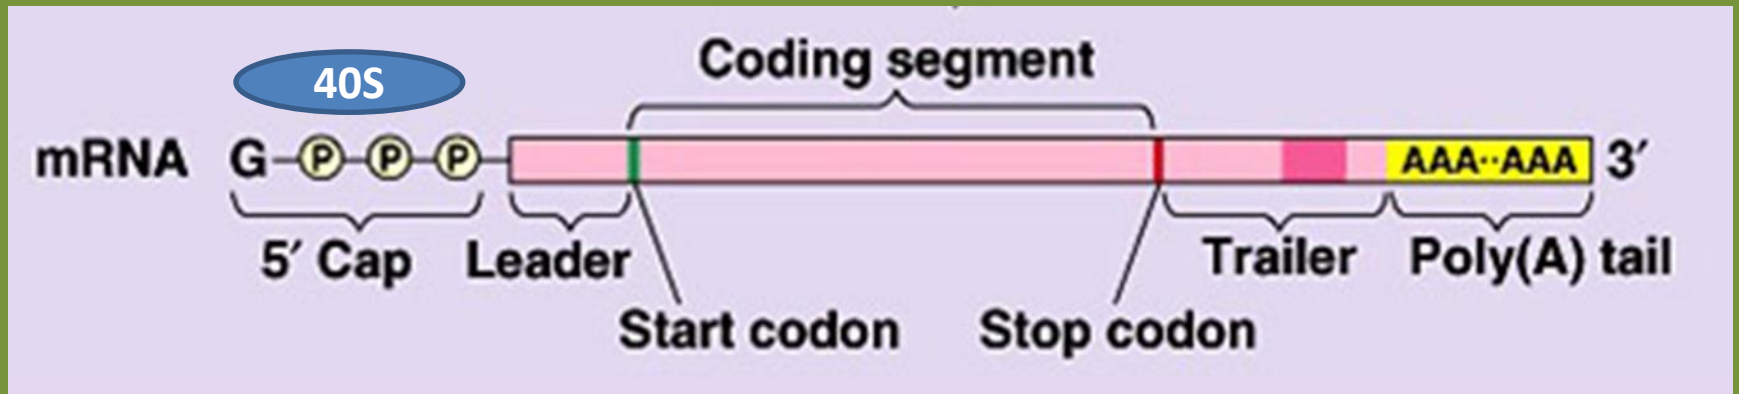

## t-RNA<sub>i</sub><sup>met</sup> have

- 1) unusual tertiary structure and
- 2) phosphorylated 2' ribose of base 64

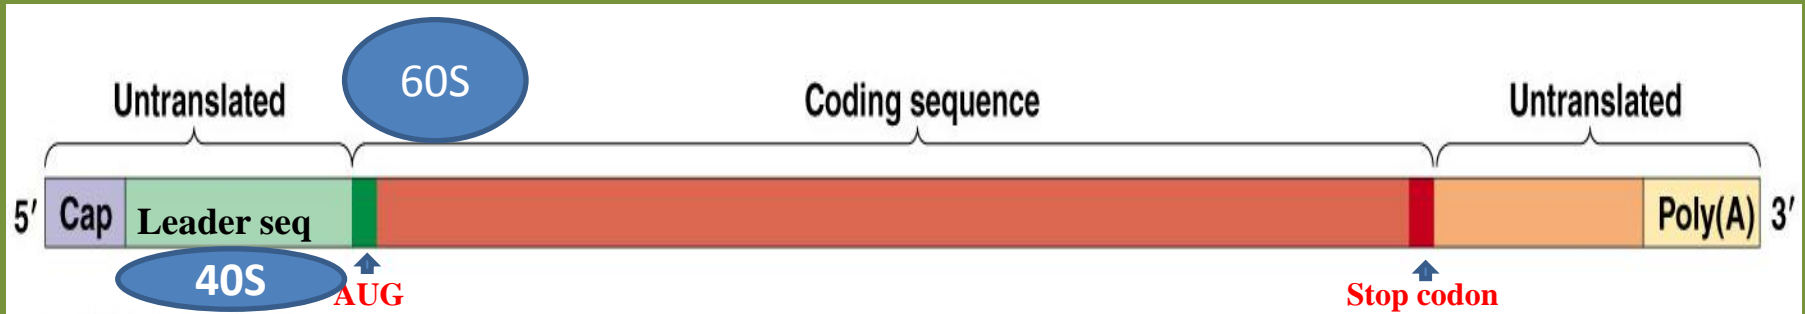

## In eukaryotes -

- ❖ Small subunit is involved in recognition and binding of mRNA and tRNA. Large subunit is involved in enzymatic reactions.
- ❖ 40S subunit recognise 5' cap, bind at or near it and then migrate towards first AUG

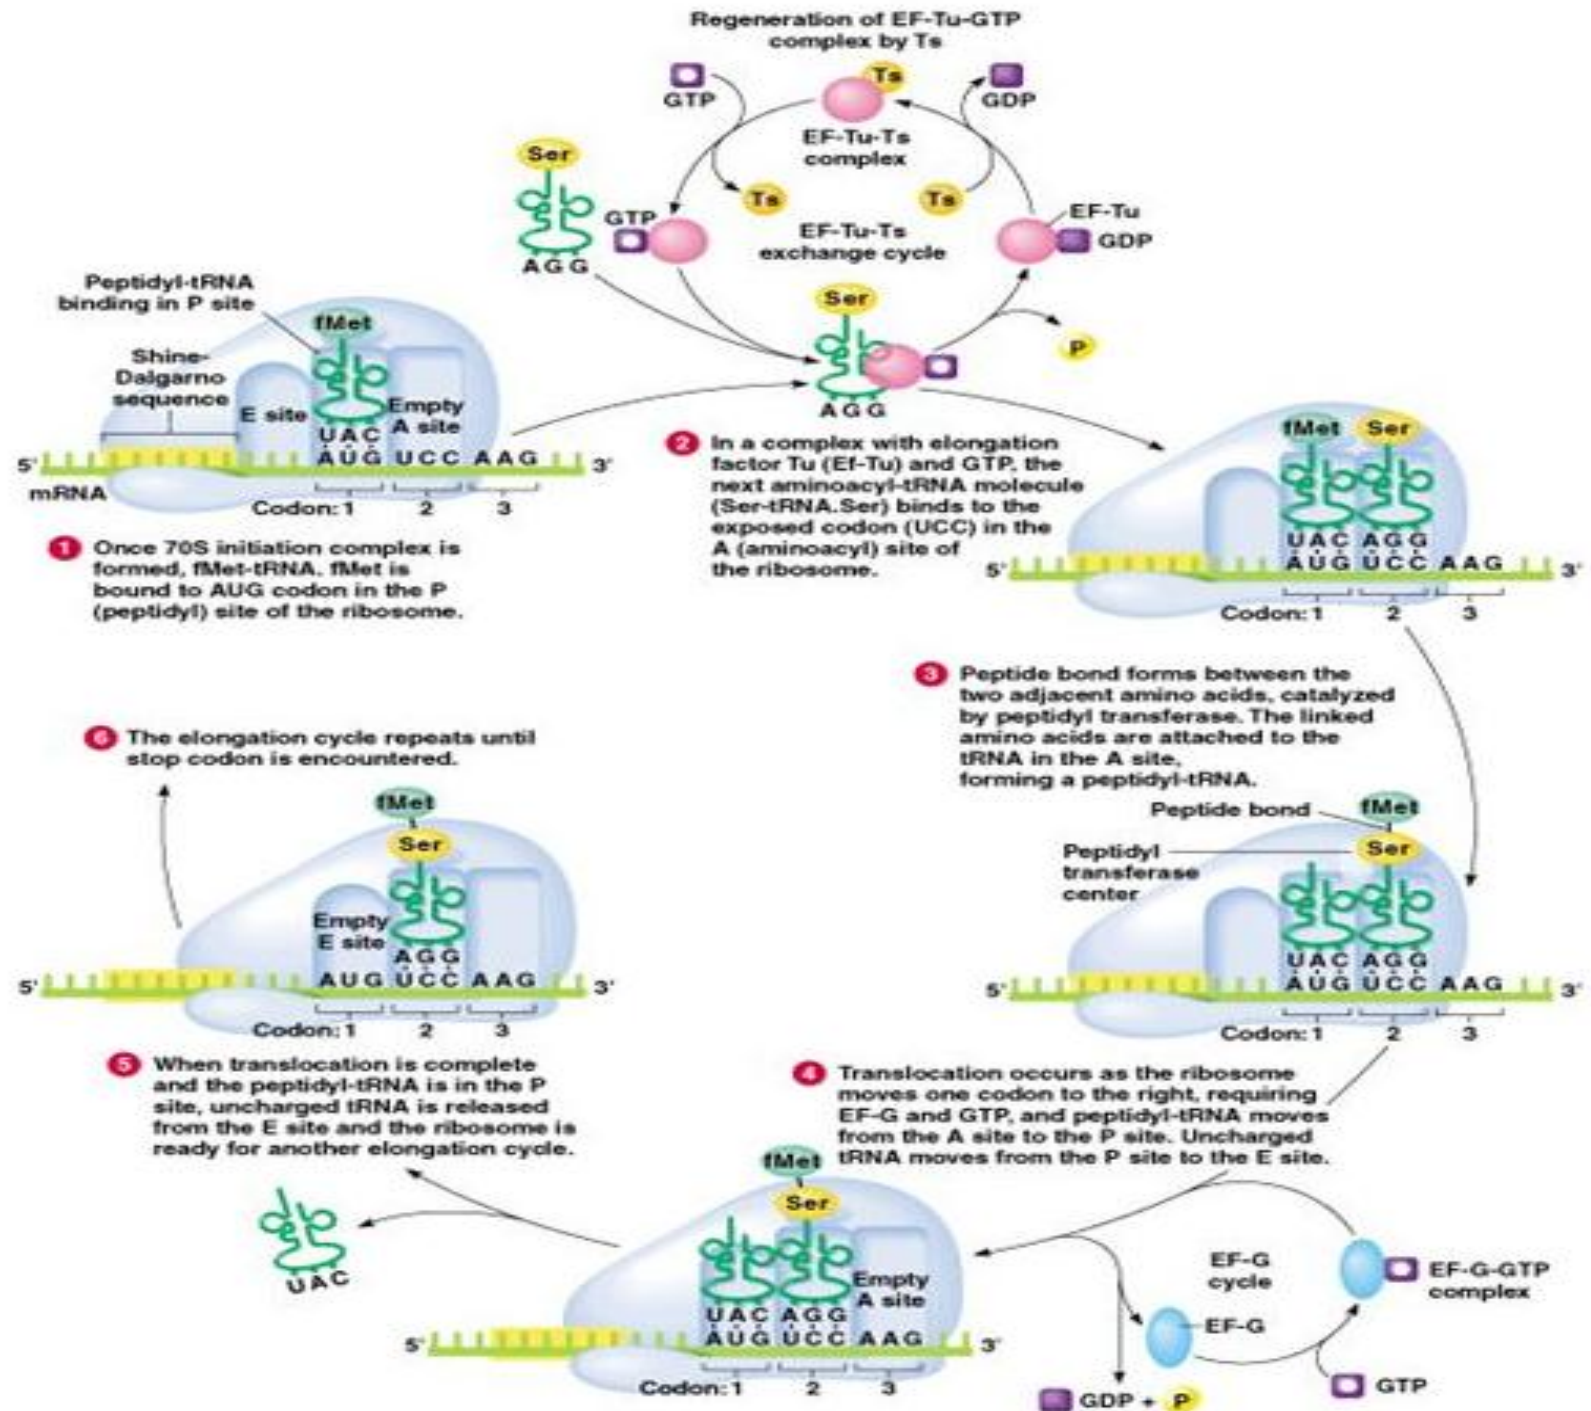

## Eukaryotic processed m-RNA for translation

- ❖ Leader sequence (variable in length) if within ~40 bases from 5' cap, the initiating codon automatically covered by ribosome binding at 5' end.
- ❖ Otherwise ribosome have to move till it reaches initiating codon.
- ❖ Protein factor eIF-4A binds to 5' cap, it unwinds the secondary structure of mRNA
- ❖ Further away from cap, eIF-4A needs eIF-4B. ATP is required for unwinding.
- ❖ **Only 40S subunit migrates. 60S joins at the initiating codon**
- ❖ A sequence GCCPuCC**AUG**G is required for cessation of migration

**Translocation**

Other incoming aminoacyl tRNA is welcomed at A site, then carried to P site, and then exit through E site after spending some time.

## 7. ELONGATION OF TRANSLATION

- Three key events for correct addition of each amino acids:
  - 1) Correct aminoacyl-tRNA is loaded to the A site of the ribosome as dictated by the A site codon
  - 2) Peptidyl transferase reaction
  - 3) Translocation of peptidyl tRNA from A site of ribosome to the P site of ribosome.
- Two proteins control these events called Elongation factors, both of which use energy from GTP binding and hydrolysis
- **EF-Tu** – It “escorts” aminoacyl tRNAs to the ribosomes
- **EF-G** – it derieves translocation of tRNA and mRNA

## In Prokaryotes

### 3 Release Factors (RF1, RF2 and RF3)

RF1 recognizes **UAA** and **UAG**

RF2 recognizes **UAA** and **UGA**

RF3 plays **stimulatory** role

## In eukaryotes

Only 1 release factor: eRF
